Script-Controlled ACL – Restrict Record Access Based on Field Value

Phase 3 - Project Design

Purpose: Design the ACL logic, data conditions, access flow, and security behavior before implementation.

Section Details

Access Control Design	Record request/access → identify the target record → evaluate the required field value → execute the ACL script → allow access when the condition is satisfied → deny access when the condition is not satisfied.
Data Design	Use the target record, the field selected for access control, the field value, the current user information, and the applicable roles/permissions as inputs for the access-control decision.
Script Design	Create a Script-Controlled ACL that checks the configured field value and applies the required access condition. The script should return an access decision that permits authorized users and restricts unauthorized access.
Interface Design	Use the standard ServiceNow record interface while ensuring that restricted records are not accessible to users who do not satisfy the ACL condition. Authorized users should retain normal record access.

Project Note: This phase document is prepared for organizing the TN Skills project evidence and can be supplemented with your actual ServiceNow ACL configuration, target table and field, script logic, roles, test scenarios, and screenshots.
